Question 1

(a) Characteristic polynomial of T is

$$-(t-2)^5(t-3)^2$$

For eigenvalue $\lambda = 2$,

(b) $\dim(E_2) = 2$ and $\dim(K_2) = 5$

(c) smallest $p = 3$

(d) $\dim(\text{Ker}(T|_{K_2} - 2)) = 2$, $\dim(\text{Ker}(T|_{K_2} - 2)^2) = 4$ and $\dim(\text{Ker}(T|_{K_2} - 2)^3) = 5$.

For eigenvalue $\lambda = 3$,

(b) $\dim(E_3) = 2$ and $\dim(K_3) = 2$

(c) smallest $p = 1$

(d) $\dim(\text{Ker}(T|_{K_3} - 2)) = 2$, $\dim(\text{Ker}(T|_{K_3} - 2)^2) = 2$ and $\dim(\text{Ker}(T|_{K_3} - 2)^3) = 2$. \square

Question 2

(a) First, find characteristic polynomial of A ,

$$\begin{aligned} \det(A - tI) &= \begin{vmatrix} 11-t & -4 & -5 \\ 21 & -8-t & -11 \\ 3 & -1 & -t \end{vmatrix} \\ &= -t^3 + 3t^2 - 4 \\ &= -(t-2)^2(t+1) \end{aligned}$$

A has eigenvalues 2 and -1 .

- For eigenvalue 2,

$$A - 2I = \begin{pmatrix} 9 & -4 & -5 \\ 21 & -10 & -11 \\ 3 & -1 & -2 \end{pmatrix}$$

has kernel $\text{span}\{(1, 1, 1)^t\}$. The other basis vector for K_2 can be found by solving for x such that $(A - 2I)x = (1, 1, 1)^t$. By Gauss-Jordan elimination

$$\left(\begin{array}{ccc|c} 9 & -4 & -5 & 1 \\ 21 & -10 & -11 & 1 \\ 3 & -1 & -2 & 1 \end{array} \right) \rightarrow \left(\begin{array}{ccc|c} 1 & 0 & -1 & 1 \\ 0 & 1 & -1 & 2 \\ 0 & 0 & 0 & 0 \end{array} \right).$$

It can be verified that $(A - 2I)(1, 2, 0)^t$ is indeed $(1, 1, 1)$, so $(A - 2I)^2(1, 2, 0)^t = 0$. A basis for K_2 is $\{(1, 1, 1)^t, (1, 2, 0)^t\}$.

- For eigenvalue -1 ,

$$A + I = \begin{pmatrix} 12 & -4 & -5 \\ 21 & -7 & -11 \\ 3 & -1 & 1 \end{pmatrix}$$

which has kernel $\text{span}\{(1, 3, 0)^t\}$.

Let Q be given by

$$Q := \begin{pmatrix} 1 & 1 & 1 \\ 1 & 2 & 3 \\ 1 & 0 & 0 \end{pmatrix}$$

which clearly has linearly independent columns, then from computations above,

$$\begin{aligned} AQ &= \left(2 \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} \mid \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} + 2 \begin{pmatrix} 1 \\ 2 \\ 0 \end{pmatrix} \mid -1 \begin{pmatrix} 1 \\ 3 \\ 0 \end{pmatrix} \right) \\ &= Q \begin{pmatrix} 2 & 1 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & -1 \end{pmatrix} \end{aligned}$$

so by setting J as the matrix in Jordan canonical form shown above, we have $Q^{-1}AQ = J$. \square

- (b) Find the characteristic polynomial of A ,

$$\begin{aligned} \det(A - tI) &= \begin{vmatrix} 2-t & 1 & 0 & 0 \\ 0 & 2-t & 1 & 0 \\ 0 & 0 & 3-t & 0 \\ 0 & 1 & -1 & 3-t \end{vmatrix} \\ &= (t-2)^2(t-3)^2 \end{aligned}$$

A has eigenvalues 2 and 3.

- For eigenvalue 2,

$$A - 2I = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & -1 & 1 \end{pmatrix}$$

which has kernel given by $\text{span}\{(1, 0, 0, 0)^t\}$. Using the same shortcut, solve for x in $(A -$

$2I)x = (1, 0, 0, 0)^t$, by Gauss-Jordan elimination,

$$\left(\begin{array}{cccc|c} 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 1 & -1 & 1 & 0 \end{array} \right) \rightarrow \left(\begin{array}{cccc|c} 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & -1 \\ 0 & 0 & 0 & 0 & 0 \end{array} \right)$$

A trivial verification shows that $(A - 2I)(0, 1, 0, -1)^t = (1, 0, 0, 0)^t$ indeed, so $\{(1, 0, 0, 0)^t, (0, 1, 0, -1)^t\}$ forms a basis for K_2 .

- For eigenvalue 3,

$$A - 3I = \begin{pmatrix} -1 & 1 & 0 & 0 \\ 0 & -1 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 1 & -1 & 0 \end{pmatrix}$$

which has a kernel $\text{span} \{(0, 0, 0, 1)^t, (1, 1, 1, 0)^t\}$.

Let Q be given by

$$Q := \begin{pmatrix} 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 1 \\ 0 & -1 & 1 & 0 \end{pmatrix}$$

a trivial computation shows that it has linearly independent columns, then from the computations above

$$\begin{aligned} AQ &= \left(2 \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \end{pmatrix} \middle| \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \end{pmatrix} + 2 \begin{pmatrix} 0 \\ 1 \\ 0 \\ -1 \end{pmatrix} \middle| 3 \begin{pmatrix} 0 \\ 0 \\ 0 \\ 1 \end{pmatrix} \middle| 3 \begin{pmatrix} 1 \\ 1 \\ 1 \\ 0 \end{pmatrix} \right) \\ &= Q \begin{pmatrix} 2 & 1 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 3 & 0 \\ 0 & 0 & 0 & 3 \end{pmatrix} \end{aligned}$$

so by setting J as the matrix in Jordan canonical form shown above, we have $Q^{-1}AQ = J$. \square

Question 3

- (a) Let $\mathcal{B} := (e^t, te^t, t^2e^t, t^3e^t, e^{3t}, te^{3t})$, to compute $[T]_{\mathcal{B}}$, first find out where T sends the basis to,

$$\begin{aligned} T(e^t) &= e^t \\ T(te^t) &= e^t + te^t \\ T(t^2e^t) &= 2te^t + t^2e^t \\ T(t^3e^t) &= 3t^2e^t + t^3e^t \\ T(e^{3t}) &= 3e^{3t} \\ T(te^{3t}) &= e^{3t} + 3te^{3t} \end{aligned}$$

which is enough information to consolidate the matrix representation of T with respect to \mathcal{B} ,

$$[T]_{\mathcal{B}} = \begin{pmatrix} 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 2 & 0 & 0 & 0 \\ 0 & 0 & 1 & 3 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 3 & 1 \\ 0 & 0 & 0 & 0 & 0 & 3 \end{pmatrix}.$$

$[T]_{\mathcal{B}}$ is *almost* in Jordan canonical form, we just need to find vectors $c, d \in V$ such that $(T - I)c = te^t$ and $(T - I)d = c$, which are as given

$$\begin{aligned} T\left(\frac{1}{2}t^2e^t\right) &= \frac{1}{2}t^2e^t + te^t \\ T\left(\frac{1}{6}t^3e^t\right) &= \frac{1}{6}t^3e^t + \frac{1}{2}t^2e^t \end{aligned}$$

then it becomes clear that with respect to a new ordered basis $\mathcal{B}' := (e^t, te^t, \frac{1}{2}t^2e^t, \frac{1}{6}t^3e^t, e^{3t}, te^{3t})$,

$$[T]_{\mathcal{B}'} = \begin{pmatrix} 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 3 & 1 \\ 0 & 0 & 0 & 0 & 0 & 3 \end{pmatrix}.$$

□

- (b) Let $\mathcal{B} := \left(\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} \right)$ be an ordered basis for V . First find out where T sends this basis to

$$T \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} 2 & 0 \\ 0 & 0 \end{pmatrix}$$

$$T \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} 0 & 3 \\ -1 & 0 \end{pmatrix}$$

$$T \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} 1 & -1 \\ 3 & 0 \end{pmatrix}$$

$$T \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ 0 & 2 \end{pmatrix}$$

this is enough information to find $[T]_{\mathcal{B}}$

$$[T]_{\mathcal{B}} = \begin{pmatrix} 2 & 0 & 1 & 0 \\ 0 & 3 & -1 & 1 \\ 0 & -1 & 3 & 0 \\ 0 & 0 & 0 & 2 \end{pmatrix}.$$

Proceed to decompose T into Jordan form (if possible), the characteristic polynomial is

$$\begin{aligned} \det([T]_{\mathcal{B}} - tI) &= \begin{vmatrix} 2-t & 0 & 1 & 0 \\ 0 & 3-t & -1 & 1 \\ 0 & -1 & 3-t & 0 \\ 0 & 0 & 0 & 2-t \end{vmatrix} \\ &= (2-t)^2 \begin{vmatrix} 3-t & -1 \\ -1 & 3-t \end{vmatrix} \\ &= (2-t)^2 [(3-t)^2 - 1] \\ &= (t-2)^3(t-4) \end{aligned}$$

For now, take all column vectors with respect to ordered basis \mathcal{B} .

- For eigenvalue 4,

$$[T]_{\mathcal{B}} - 4I = \begin{pmatrix} -2 & 0 & 1 & 0 \\ 0 & -1 & -1 & 1 \\ 0 & -1 & -1 & 0 \\ 0 & 0 & 0 & -2 \end{pmatrix}$$

which has kernel given by $\text{span} \{ (1, -2, 2, 0)^t \}$.

- For eigenvalue 2,

$$[T]_{\mathcal{B}} - 2I = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 1 & -1 & 1 \\ 0 & -1 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

observe that $\ker([T]_{\mathcal{B}} - 2I) = \text{span} \{ (1, 0, 0, 0)^t \}$.

Solve for $x \in V$ such that $([T]_{\mathcal{B}} - 2I)[x]_{\mathcal{B}} = (1, 0, 0, 0)^t$, by Gauss-Jordan elimination

$$\left(\begin{array}{cccc|c} 0 & 0 & 1 & 0 & 1 \\ 0 & 1 & -1 & 1 & 0 \\ 0 & -1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{array} \right) \rightarrow \left(\begin{array}{cccc|c} 0 & 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{array} \right)$$

we have $([T]_{\mathcal{B}} - 2I)(0, 1, 1, 0)^t = (1, 0, 0, 0)^t$.

Next, solve for $y \in V$ such that $([T]_{\mathcal{B}} - 2I)[y]_{\mathcal{B}} = (0, 1, 1, 0)^t$, by Gauss-Jordan elimination

$$\left(\begin{array}{cccc|c} 0 & 0 & 1 & 0 & 0 \\ 0 & 1 & -1 & 1 & 1 \\ 0 & -1 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 \end{array} \right) \rightarrow \left(\begin{array}{cccc|c} 0 & 1 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 2 \\ 0 & 0 & 0 & 0 & 0 \end{array} \right)$$

so we have $([T]_{\mathcal{B}} - 2I)(0, -1, 0, 2)^t = (0, 1, 1, 0)^t$.

Then from the computations above, we see that with respect to the new ordered basis $\mathcal{B}' := \left(\begin{pmatrix} 1 & -2 \\ 2 & 0 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \begin{pmatrix} 0 & -1 \\ 0 & 2 \end{pmatrix} \right)$,

$$[T]_{\mathcal{B}'} = \begin{pmatrix} 4 & 0 & 0 & 0 \\ 0 & 2 & 1 & 0 \\ 0 & 0 & 2 & 1 \\ 0 & 0 & 0 & 2 \end{pmatrix}.$$

□

Question 4

For any $r \in \mathbb{N}$, let $P_r \in \mathbb{M}_r(K)$ denote the $r \times r$ matrix

$$P_r := \begin{pmatrix} 0 & \cdots & 0 & 1 \\ 0 & \cdots & 1 & 0 \\ \vdots & \ddots & \vdots & \vdots \\ 1 & \cdots & 0 & 0 \end{pmatrix}.$$

It can easily be verified that $P_r P_r = I_r$. Observe that post-multiplication by P_r reverses the columns, while pre-multiplication by P_r will reverse the rows, so $A^t = P_n A P_n$. A and A^t having the same Jordan form would be a simple corollary. \square

(Did I just defeat the point of this question?)

Question 4 (again)

It is obvious that A and A^t has the same characteristic polynomial, and hence the same eigenvalues. For any eigenvalue λ of A and A^t , observe that $(A - \lambda I)^t = A^t - \lambda I$. For any $r \in \mathbb{Z}_{>0}$, $((A - \lambda I)^r)^t = ((A - \lambda I)^t)^r = (A^t - \lambda I)^r$. Then because row rank is the same as column rank, $(A - \lambda I)^r$ and $(A^t - \lambda I)^r$ have the same rank. From this we can conclude that for each eigenvalue λ , A and A^t have the same associated dot diagrams, hence the same Jordan blocks. Therefore A and A^t have the same Jordan form.

So we have $\exists Q, R \in \text{GL}_n(K)$, $J \in \mathbb{M}_n(K)$ with J in Jordan form such that $J = Q A Q^{-1} = R A^t R^{-1}$. Then $A = Q^{-1} R A^t R^{-1} Q$, which shows that $A \sim A^t$. \square

Question 5

(a) Let $N := A - \lambda I$ in $\mathbb{M}_n(K)$. For any $r \in \mathbb{N}$, computation shows that

$$N^r(i, j) = \delta(i + r, j) = \begin{cases} 1 & \text{if } i + r = j, \\ 0 & \text{otherwise.} \end{cases}$$

(b) Let $D := \lambda I$, then $A = D + N$, note that $DN = ND$. Since they commute, the binomial

theorem applies, then for any $r \in \mathbb{N}$ with $r \geq n$,

$$\begin{aligned}
 A^r &= (D + N)^r \\
 &= \sum_{k=0}^r \binom{r}{k} D^{r-k} N^k \\
 &= \sum_{k=0}^{n-1} \binom{r}{k} \lambda^{r-k} N^k \\
 A^r(i, j) &= \sum_{k=0}^{n-1} \binom{r}{k} \lambda^{r-k} N^k(i, j) \\
 &= \sum_{k=0}^{n-1} \binom{r}{k} \lambda^{r-k} \delta(i+k, j)
 \end{aligned}$$

the Kronecker delta reduces the sum to a single term if $i \leq j$,

$$A^r(i, j) = \begin{cases} \binom{r}{k} \lambda^{r-k} & \text{if } \exists k \in \mathbb{N}. i+k = j, \\ 0 & \text{otherwise.} \end{cases}$$

□

Question 6

$$A = \begin{pmatrix} 1 & 1 & \cdots & 1 \\ 1 & 1 & \cdots & 1 \\ \vdots & \vdots & \ddots & \vdots \\ 1 & 1 & \cdots & 1 \end{pmatrix} \in \mathbb{M}_n(\mathbb{F}_p)$$

(a) The characteristic polynomial of A is

$$\begin{aligned}
 \det(A - tI) &= \begin{vmatrix} 1-t & 1 & \cdots & 1 \\ 1 & 1-t & \cdots & 1 \\ \vdots & \vdots & \ddots & \vdots \\ 1 & 1 & \cdots & 1-t \end{vmatrix} \\
 &\quad \downarrow \text{add row 2, \dots, } n \text{ to row 1} \\
 &= \begin{vmatrix} n-t & n-t & \cdots & n-t \\ 1 & 1-t & \cdots & 1 \\ \vdots & \vdots & \ddots & \vdots \\ 1 & 1 & \cdots & 1-t \end{vmatrix} \\
 &= \begin{vmatrix} n-t & 1 & \cdots & 1 \\ n-t & 1-t & \cdots & 1 \\ \vdots & \vdots & \ddots & \vdots \\ n-t & 1 & \cdots & 1-t \end{vmatrix} \\
 &\quad \downarrow \text{subtract row 1 from row 2, \dots, } n \\
 &= \begin{vmatrix} n-t & 1 & 1 & \cdots & 1 \\ 0 & -t & 0 & \cdots & 0 \\ 0 & 0 & -t & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & -t \end{vmatrix} \\
 &= (n-t)(-t)^{n-1} \\
 &= (-1)^n (t^n - nt^{n-1}) \quad \square
 \end{aligned}$$

(b) From (a), A has characteristic polynomial $(-1)^n t^{n-1}(t - n)$. So A has eigenvalues 0 and n ($n \neq 0$ as $p \nmid n$).

- For eigenvalue n , by inspection,

$$A \begin{pmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{pmatrix} = \begin{pmatrix} n \\ n \\ \vdots \\ n \end{pmatrix} = n \begin{pmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{pmatrix}$$

so $K_n = E_n$ has a basis $\text{span} \{ (1, 1, \dots, 1)^t \}$.

- For eigenvalue 0, observe that $\text{rank}(A) = 1$, so $\text{nullity}(A) = n - 1$. So A is in fact diagonalisable. By further observation, these $n - 1$ linearly independent vectors form the basis for $\ker(A)$,

$$\{ -e_1 + e_j : j \in \{2, \dots, n\} \}.$$

Define $Q \in \mathbb{M}_n(\mathbb{F}_p)$ as

$$Q := \begin{pmatrix} 1 & -1 & -1 & \dots & -1 \\ 1 & 1 & 0 & \dots & 0 \\ 1 & 0 & 1 & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & 0 & 0 & \dots & 1 \end{pmatrix}$$

As vectors from different eigen-bases are linearly independent, Q is invertible, then from computations above,

$$AQ = \begin{pmatrix} n & 0 & \dots & 0 \\ n & 0 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ n & 0 & \dots & 0 \end{pmatrix} = Q \begin{pmatrix} n & & & \\ & \bigcirc & & \\ & & \ddots & \\ & & & \bigcirc \end{pmatrix}$$

so by setting J as the diagonal matrix obtained above, we have $Q^{-1}AQ = J$. □
